### Implement Global Biosurveillance

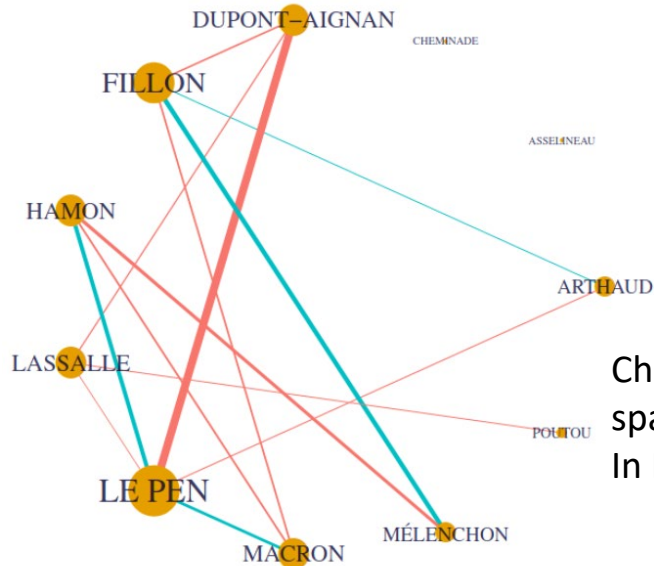

The ultimate goal of all BIOSCAN research is to lay the foundation for a comprehensive global biosurveillance system, providing real-time insight into shifts in biodiversity patterns. Effective global monitoring of biodiversity could help us to understand the shifting distributions and abundances of species, and to reduce the environmental impact of human activities.

## Logic translation

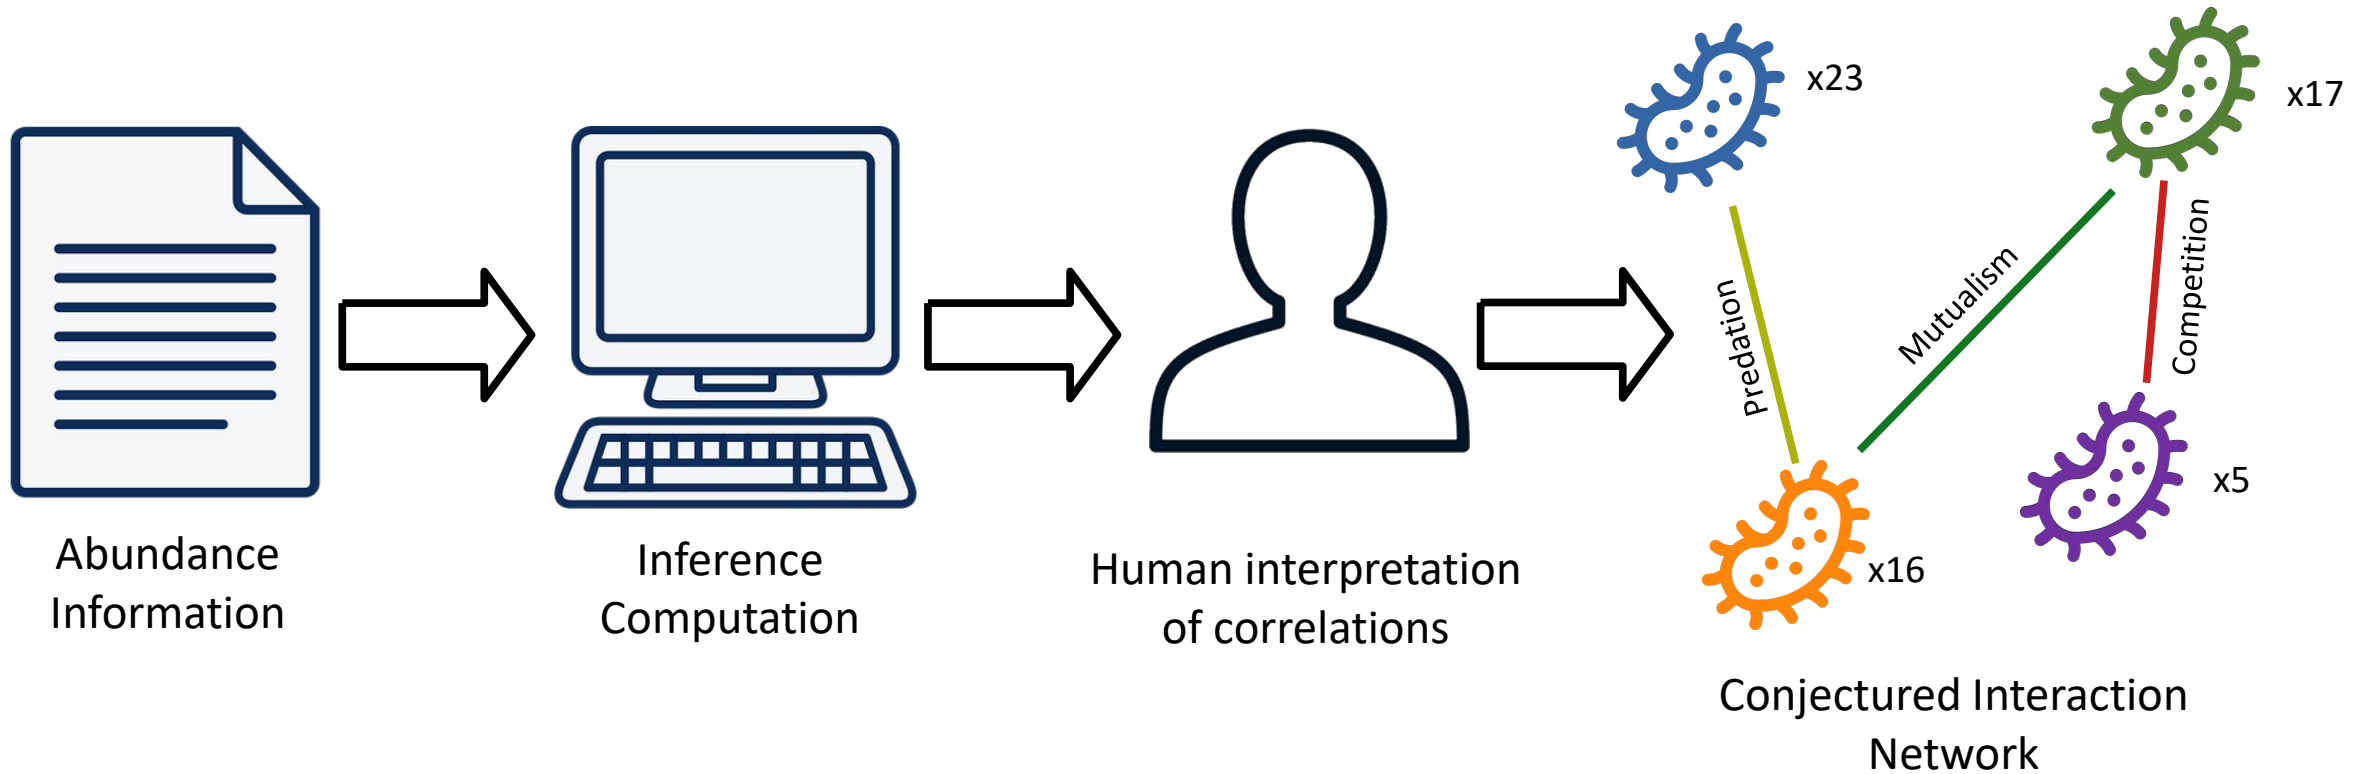

- Each sentence has a subject, object, nouns and verbs... only language structure is used for the translation
- Use previous knowledge to make (an explainable) translation

# What is the difference between association and interaction?

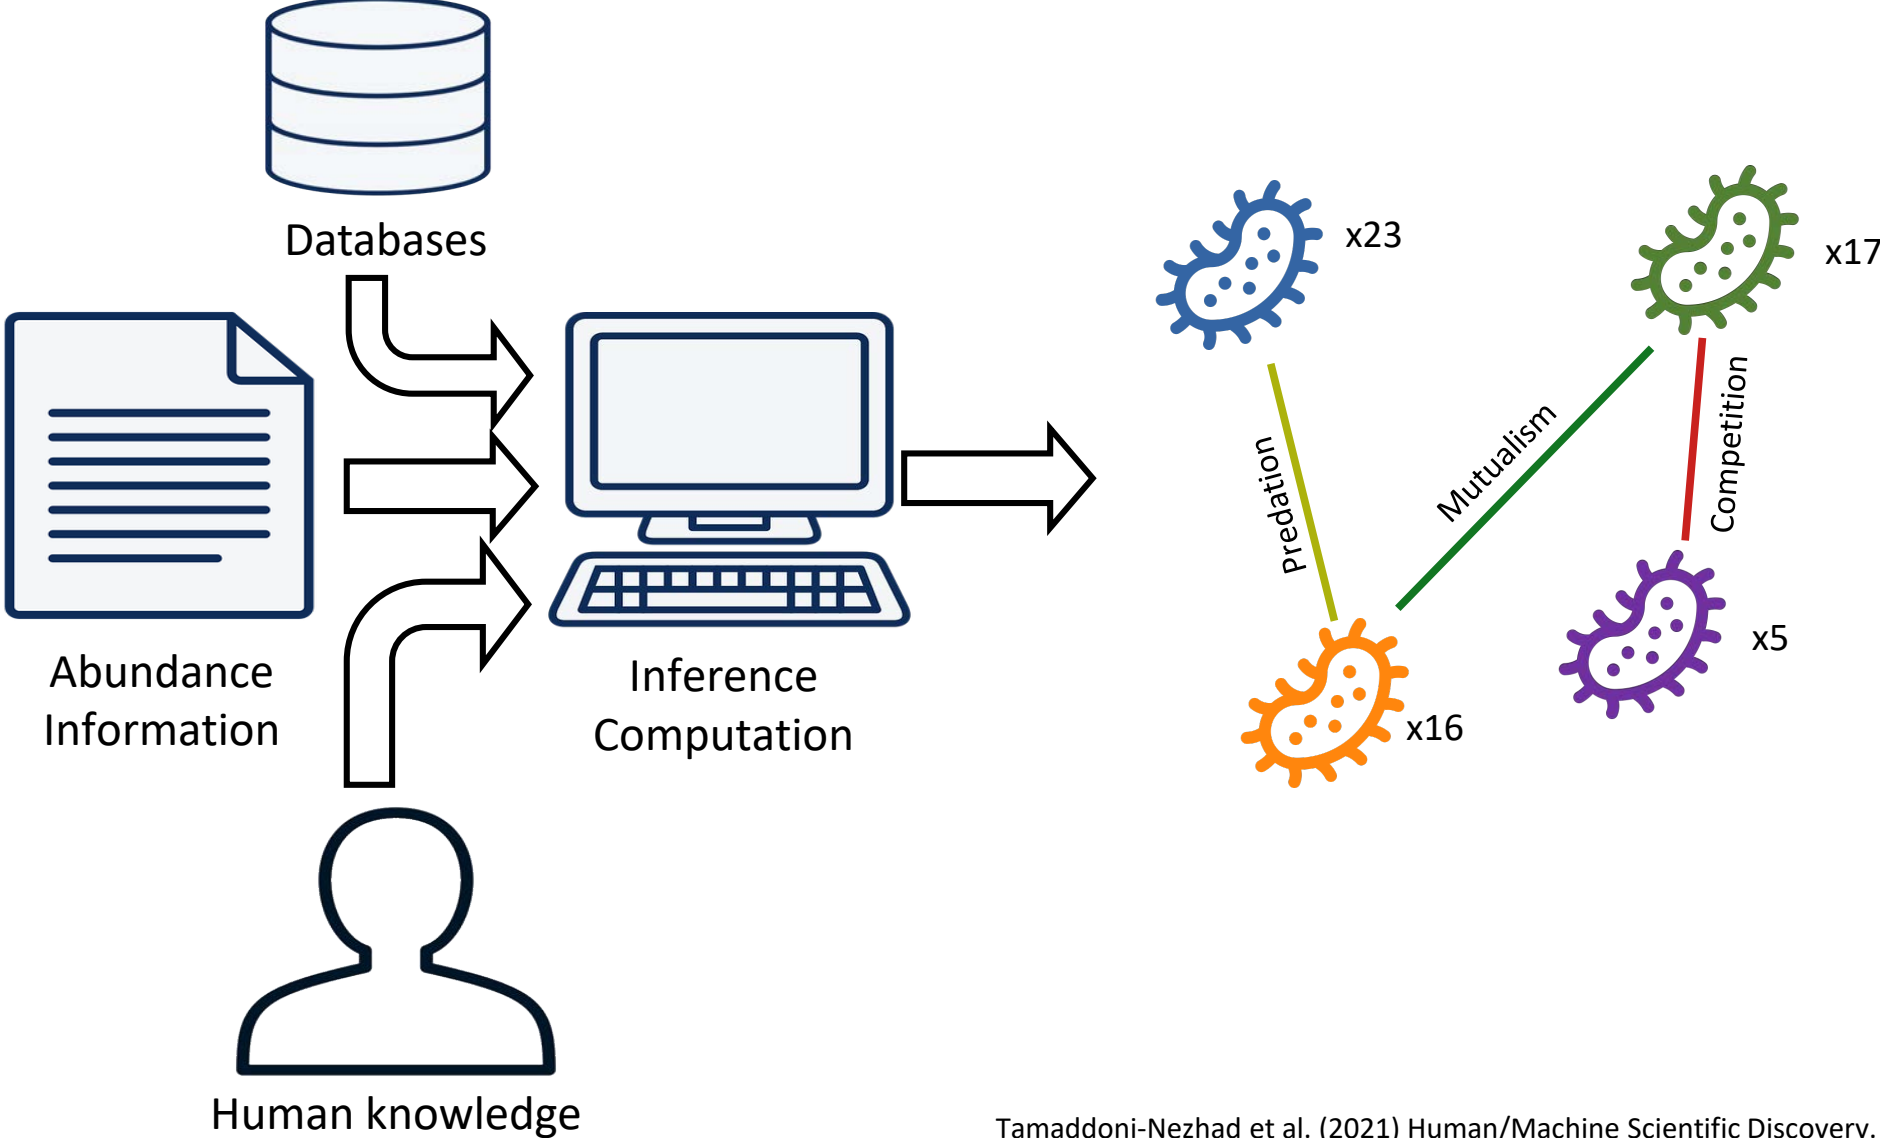

# Interaction Inference using Correlation-based Methods

# Interaction Inference using Explainable Machine Learning

# Defining logical interaction rules (hypotheses)

Interaction type	Effect on abundance of Species <sub>1</sub>	Effect on abundance of Species <sub>2</sub>	Nature of interaction
<i>Mutualism</i>	Up (+)	Up (+)	Mutual benefits to both species
<i>Competition</i>	Down (-)	Down (-)	Species have negative effect on each other
<i>Predation/Parasitism</i>	Up (+)	Down (-)	Predator/parasite develops at the expense of the prey/host
<i>Commensalism</i>	Up (+)	Null	Species <sub>1</sub> benefits while Species <sub>2</sub> is not affected
<i>Amensalism</i>	Down (-)	Null	Species <sub>2</sub> has a negative effect on Species <sub>1</sub> , but Species <sub>2</sub> is not affected

# Microorganisms as a study case

- Microorganisms play a major role in all ecosystems
- There is still a lack of knowledge about microbial communities
- Interactions are key for defining microbial communities, but are not visible
- eDNA offers the possibility of obtaining new information

# Learning from Next Generation Sequencing data

Taxa identification

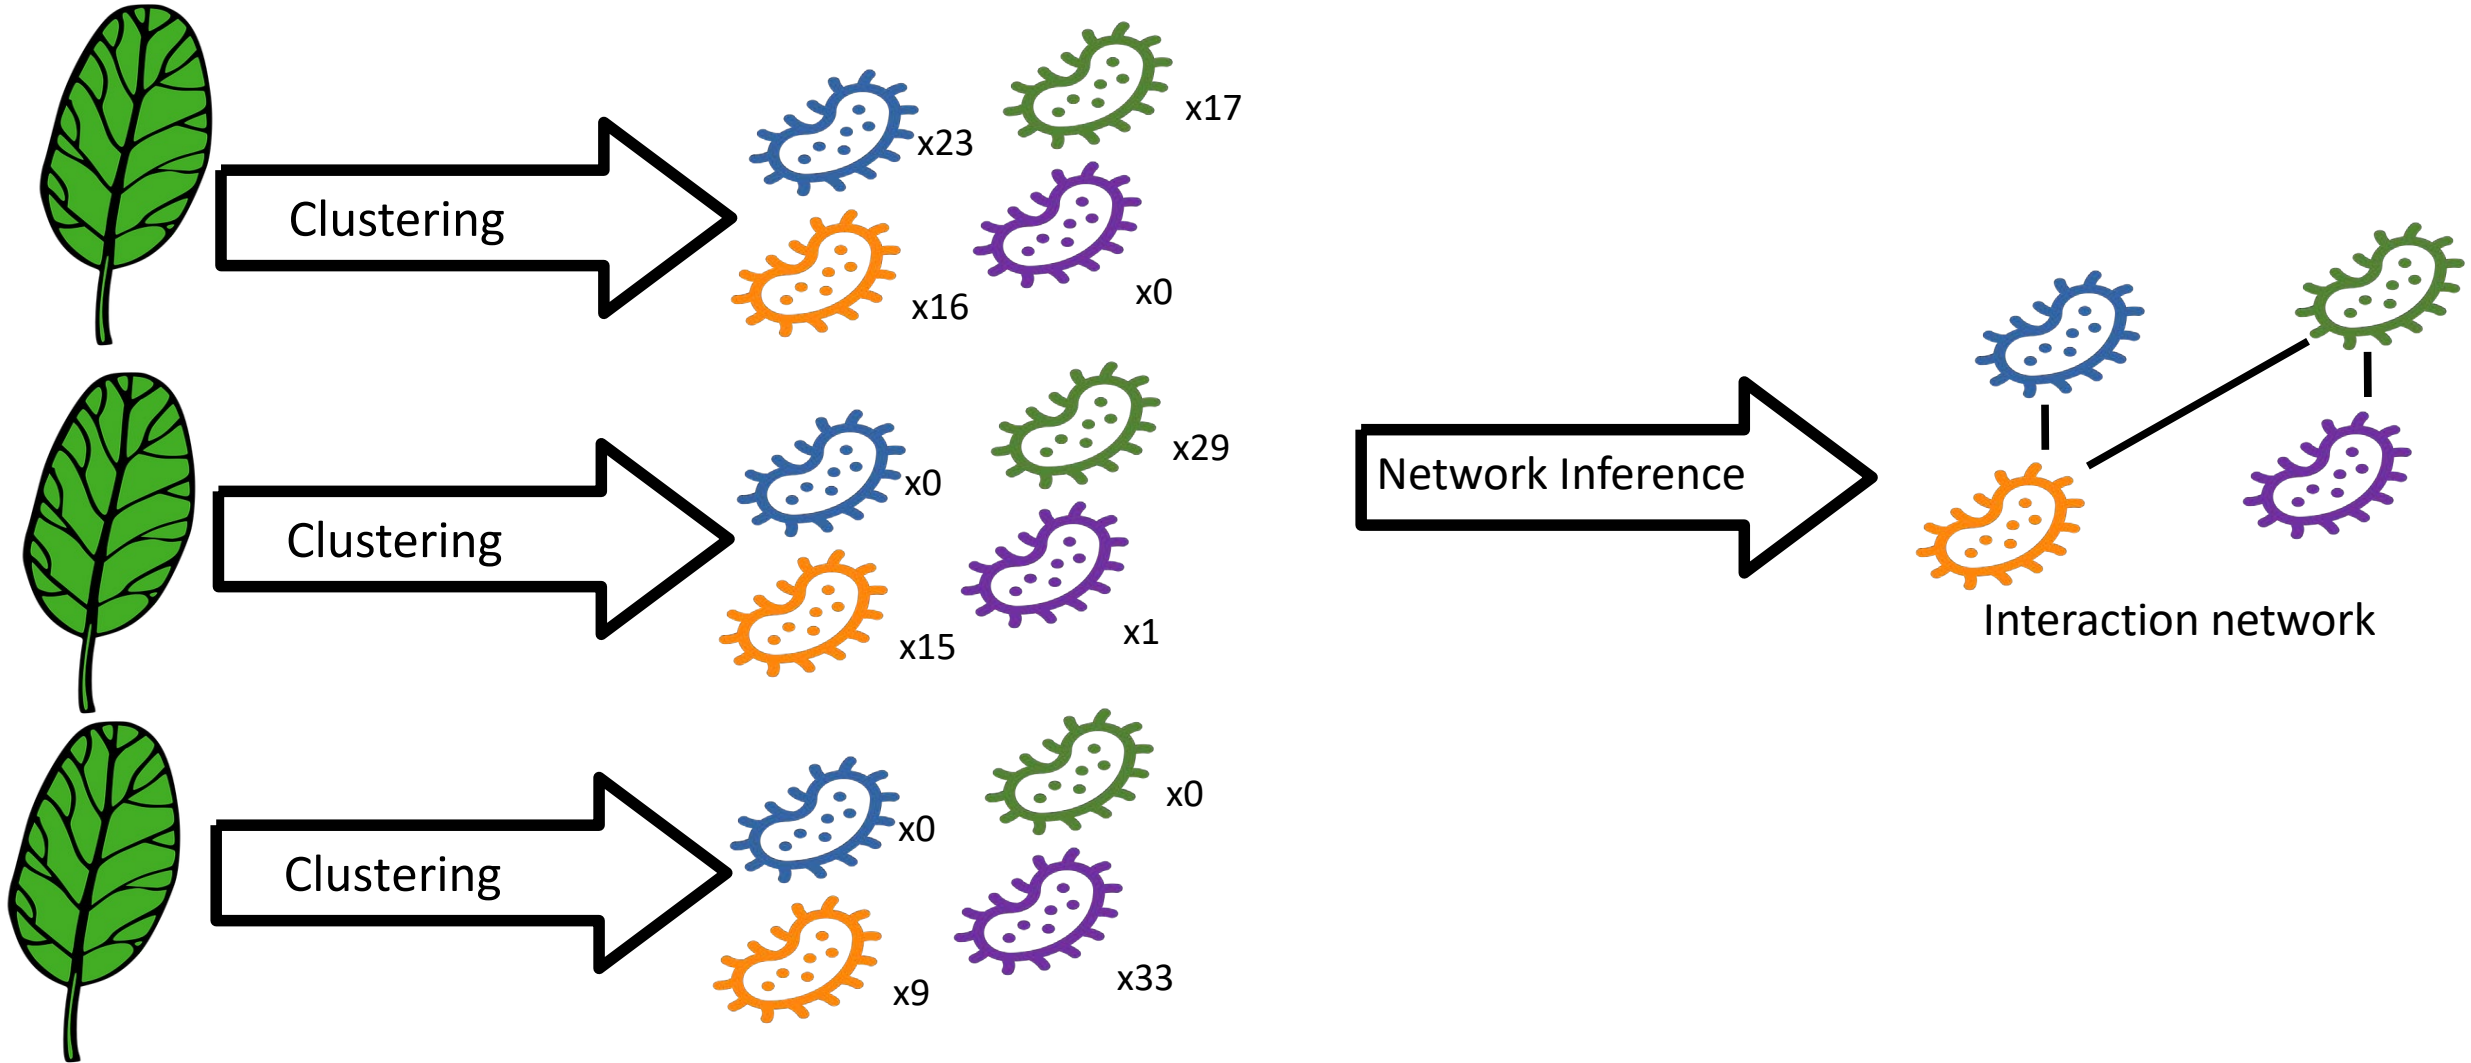

# Learning from Next Generation Sequencing data

- Clustering groups of sequences into Operational Taxonomic Units (OTUs), which represent taxonomic groups (e.g. species)
- Amplicon Sequence Variants (ASVs) are a high resolution version of the OTUs

# Learning from Next Generation Sequencing data

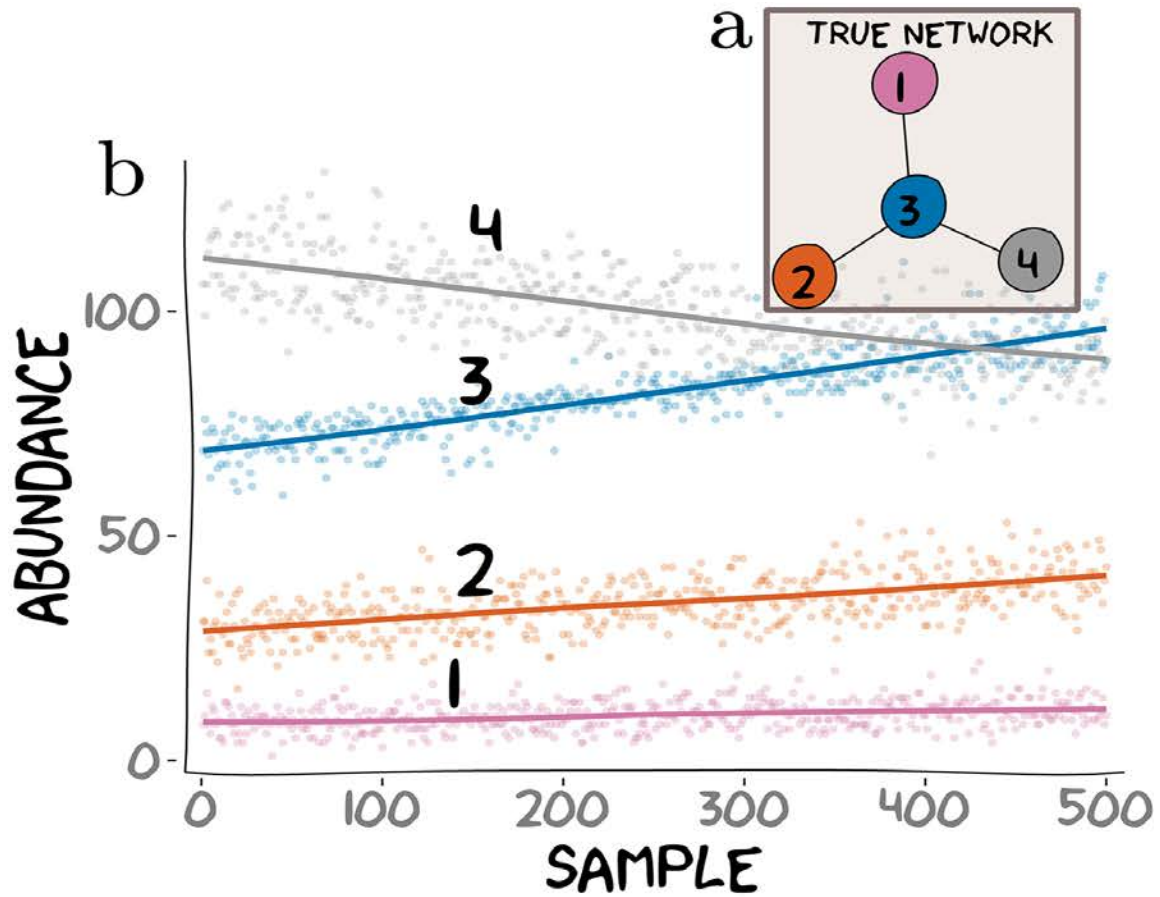

# Using correlation between abundances to infer networks

- There are numerous network inference tools that can be applied to metabarcoding systems
- These include SparCC and SPIEC-EASI, amongst others
- They detect positive and negative associations (links) that require interpretation and experimental validation

# Using correlation between abundances to infer networks

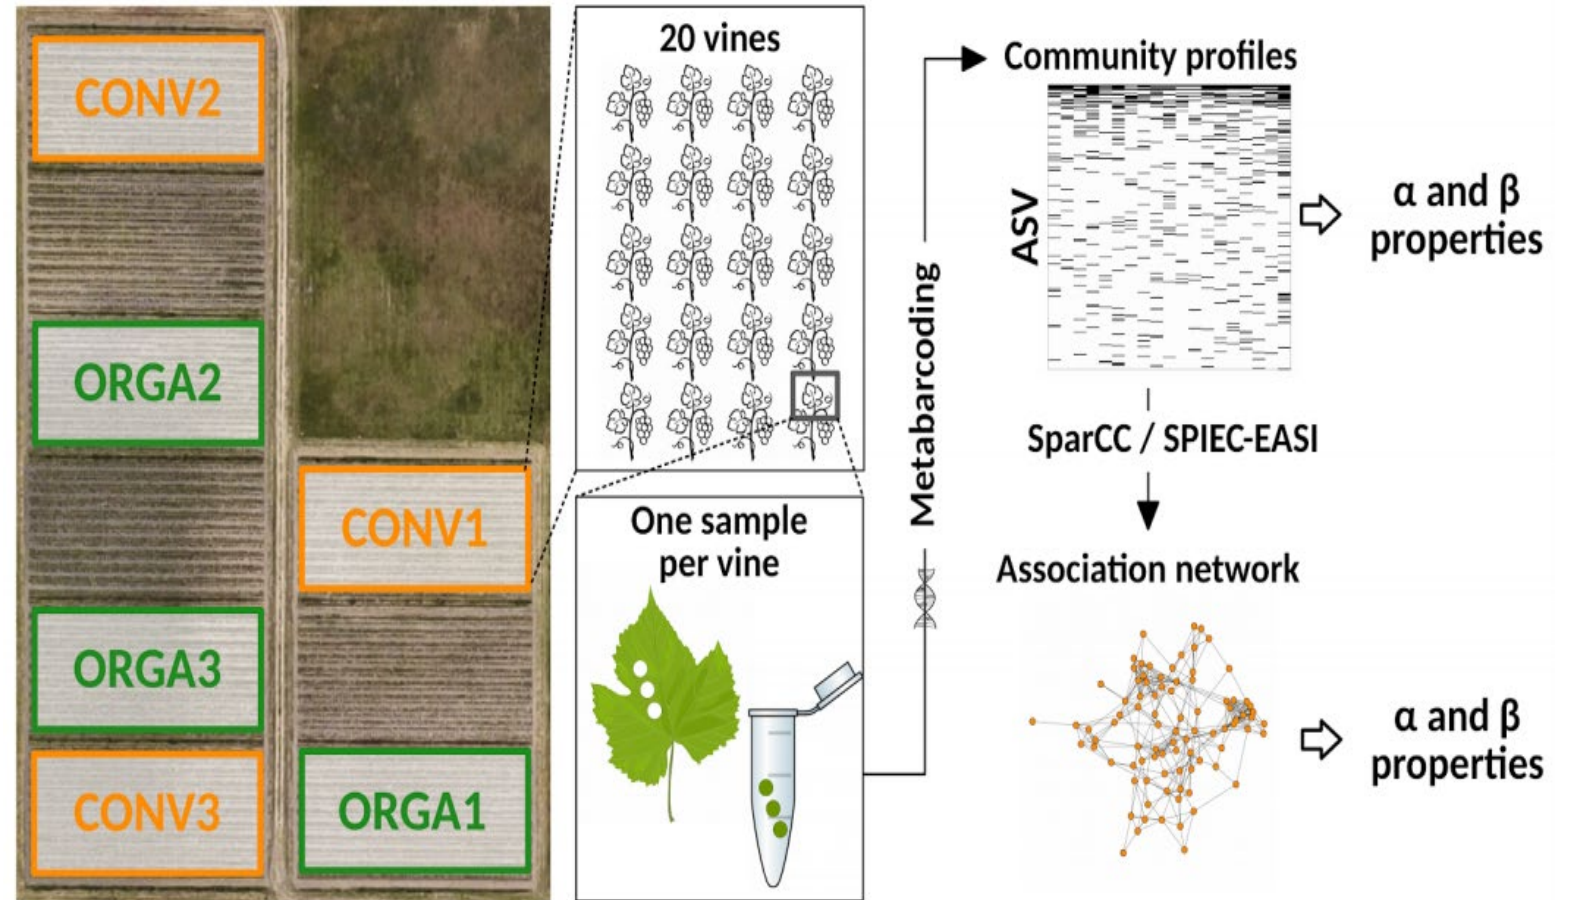

# Testing correlation tools for biomonitoring

- Microbial interaction networks change depending on the cropping system
- Are networks reconstructed from the same cropping system samples repeatable?
- Can reconstructed interaction networks capture the change in practice between cropping systems?

# Experimental design

- 3 organic and 3 conventional plots
- 20 vines sampled per plot
- ASV Clustering performed by DADA2

# Network properties

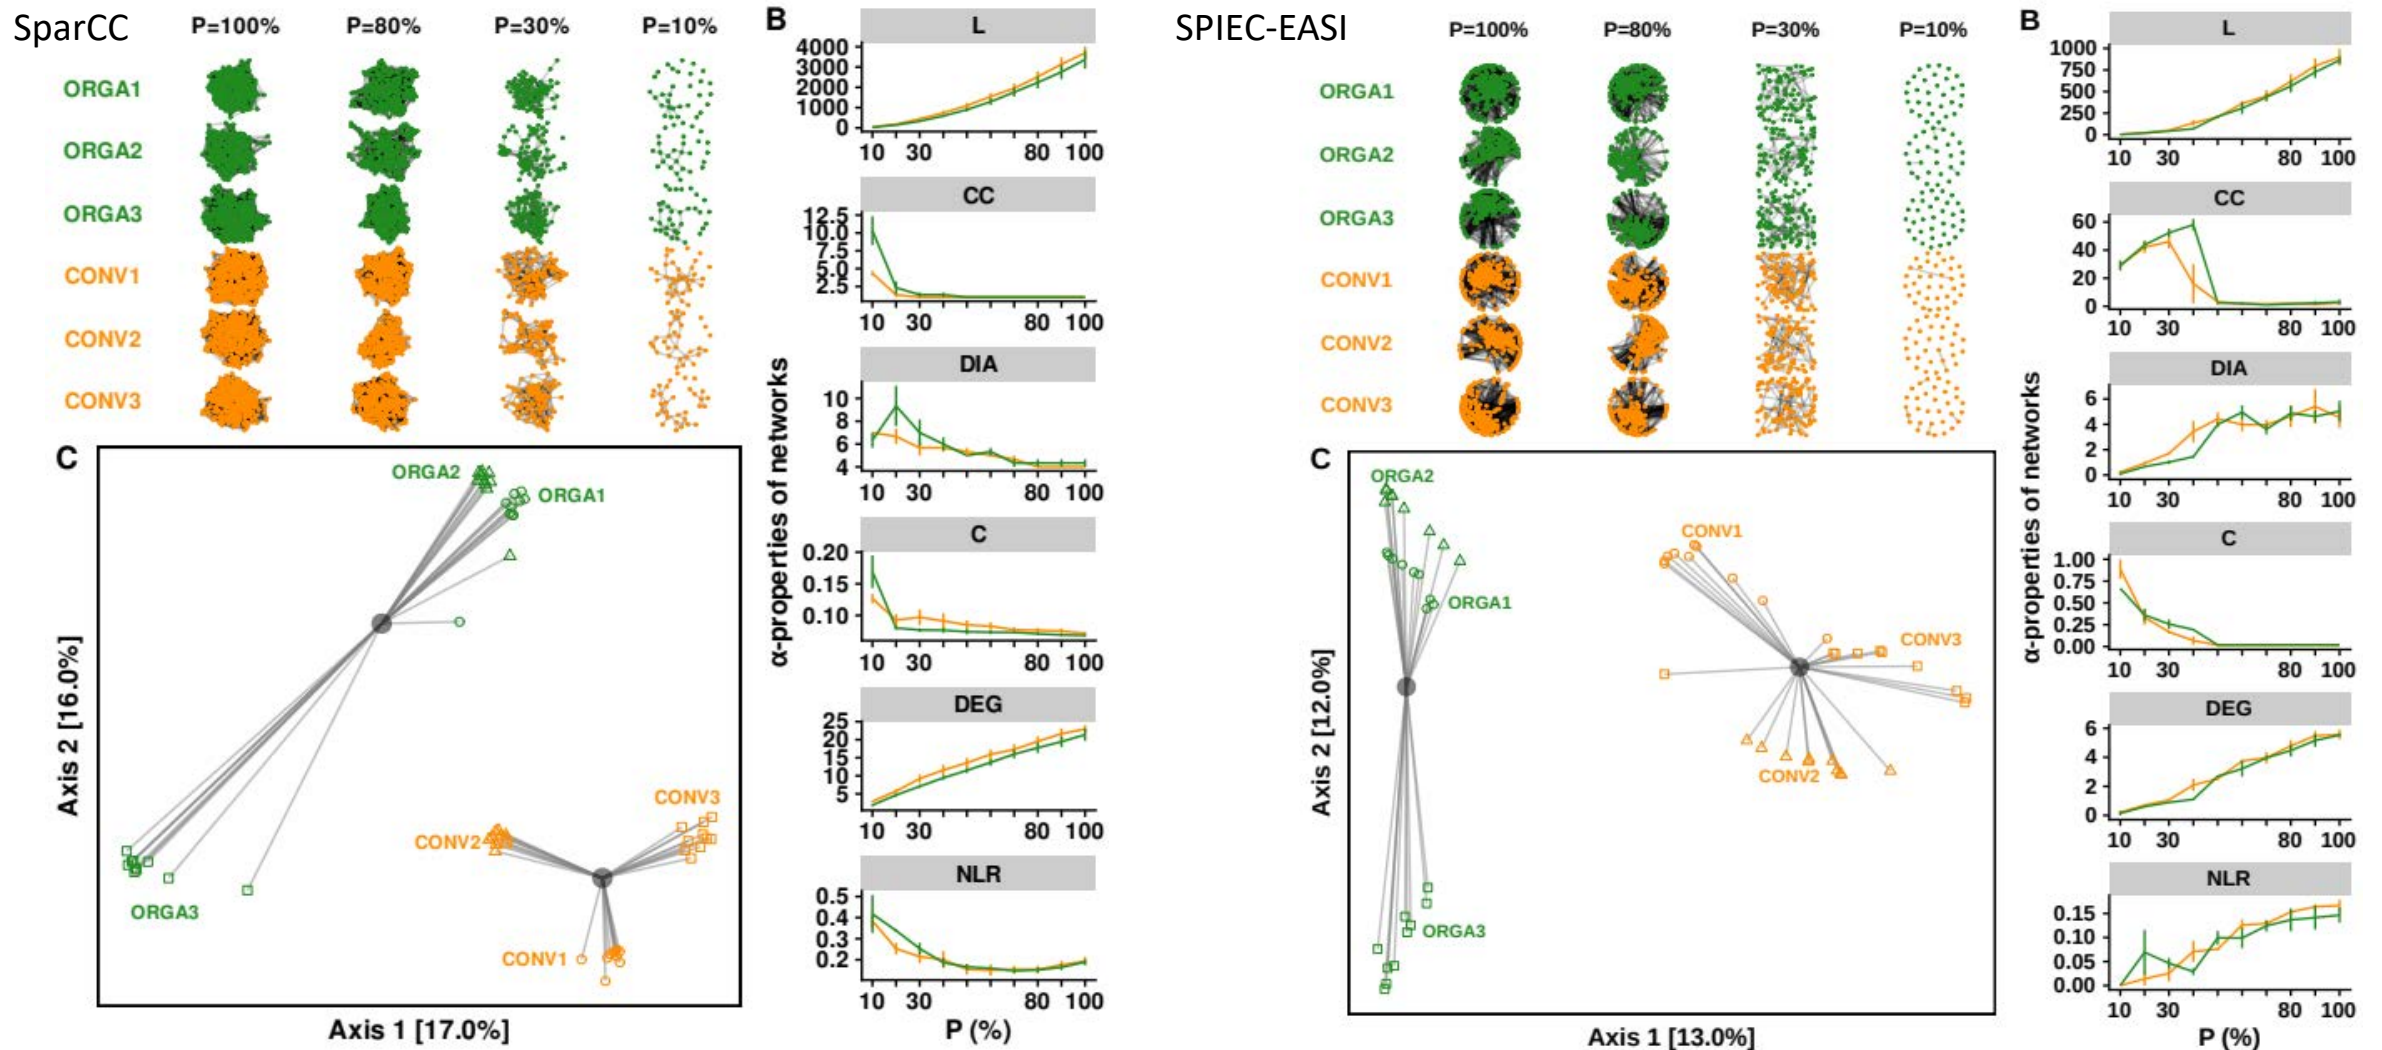

## Network $\alpha$ -properties

Number of links (L)	Total number of links	-
Connectance (C)	Fraction of the total number of possible links actually realized	Coleman & Moré, 1983
Number of connected components (CC)	Number of groups of nodes connected together	Martinez, 1992
Diameter (DIA)	The longest of all the shortest paths between two nodes	Barabási et al, 2000
Mean node degree (DEG)	Mean number of links per node	Martinez, 1992
Proportion of negative links (NLR)	Proportion of links for which the SparCC correlation is negative	Faust et al, 2015

## Network $\beta$ -properties

Topological dissimilarity (Schieber's D)	Dissimilarity of global and local network structure	Schieber et al, 2017
Association dissimilarity ( $\beta$ WN)	Overall dissimilarity of associations	Poisot et al, 2012
Association dissimilarity ( $\beta$ OS)	Dissimilarity of associations between shared ASVs	Poisot et al, 2012
Association dissimilarity ( $\beta$ ST)	Dissimilarity of associations due to ASV turnover	Poisot et al, 2012

# Network $\beta$ -properties differentiate cropping systems

# Few consensus associations were shared between networks

- Each network had several hundred ASVs and associations
- A maximum of 5 associations were found to be shared by networks from the same experimental conditions

A ORGANIC (SparCC)

B CONVENTIONAL (SparCC)

C ORGANIC (SPIEC-EASI)

D CONVENTIONAL (SPIEC-EASI)

# Conclusions

- Network  $\alpha$ -properties do not differentiate cropping systems
- Some  $\beta$ -properties differed between cropping systems
- Networks inferred from replicate cropping systems had few consensus associations
- Associations obtained by SparCC and SPIEC-EASI were classified into positive and negative correlations

# Explainable microbial network inference: The logic process

## Deduction

Rule: An interaction produces a change in abundance

Case: Two taxa interact

*Result: The abundance of at least one taxa changes*

## Induction

Case: Two taxa interact

Result: The abundance of at least one taxa changes

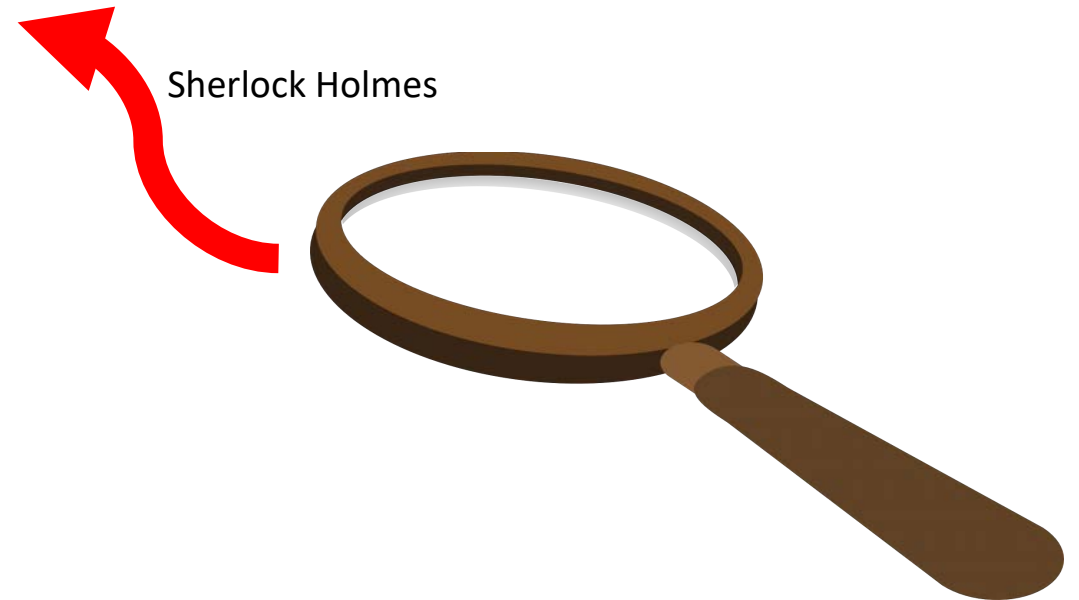

*Rule: An interaction produces a change in abundance*

## Abduction

Result: The abundance of at least one taxa changes

Rule: An interaction produces a change in abundance

*Case: Two taxa interact*

# Explainable microbial network inference: The logic process

Result: The abundance of at least one taxa changes

	x	y	z
Species1 (S1)	0	11	300
Species2 (S2)	121	27	0
Species3 (S3)	0	0	43

Logic Statements:

$abundance(x, y, s2, down)$   
 $presence(s1, x, no)$

Rule: An interaction produces a change in abundance

$effect\_up(s1, s2)$  if:  $\left\{ \begin{array}{l} abundance(x, y, s2, up) \\ presence(s1, x, no) \\ presence(s1, y, yes) \end{array} \right.$

$effect\_down(s1, s2)$  if:  $\left\{ \begin{array}{l} abundance(x, y, s2, down) \\ presence(s1, x, no) \\ presence(s1, y, yes) \end{array} \right.$

Case: Two taxa interact

$$\begin{array}{r}
 effect\_up(s1, s2) \quad 235 \\
 effect\_down(s1, s2) \quad - 157 \\
 \hline
 \text{I statistic} = \quad 78
 \end{array}$$

Compression: Amount of examples supporting the abduced fact

Predicted network

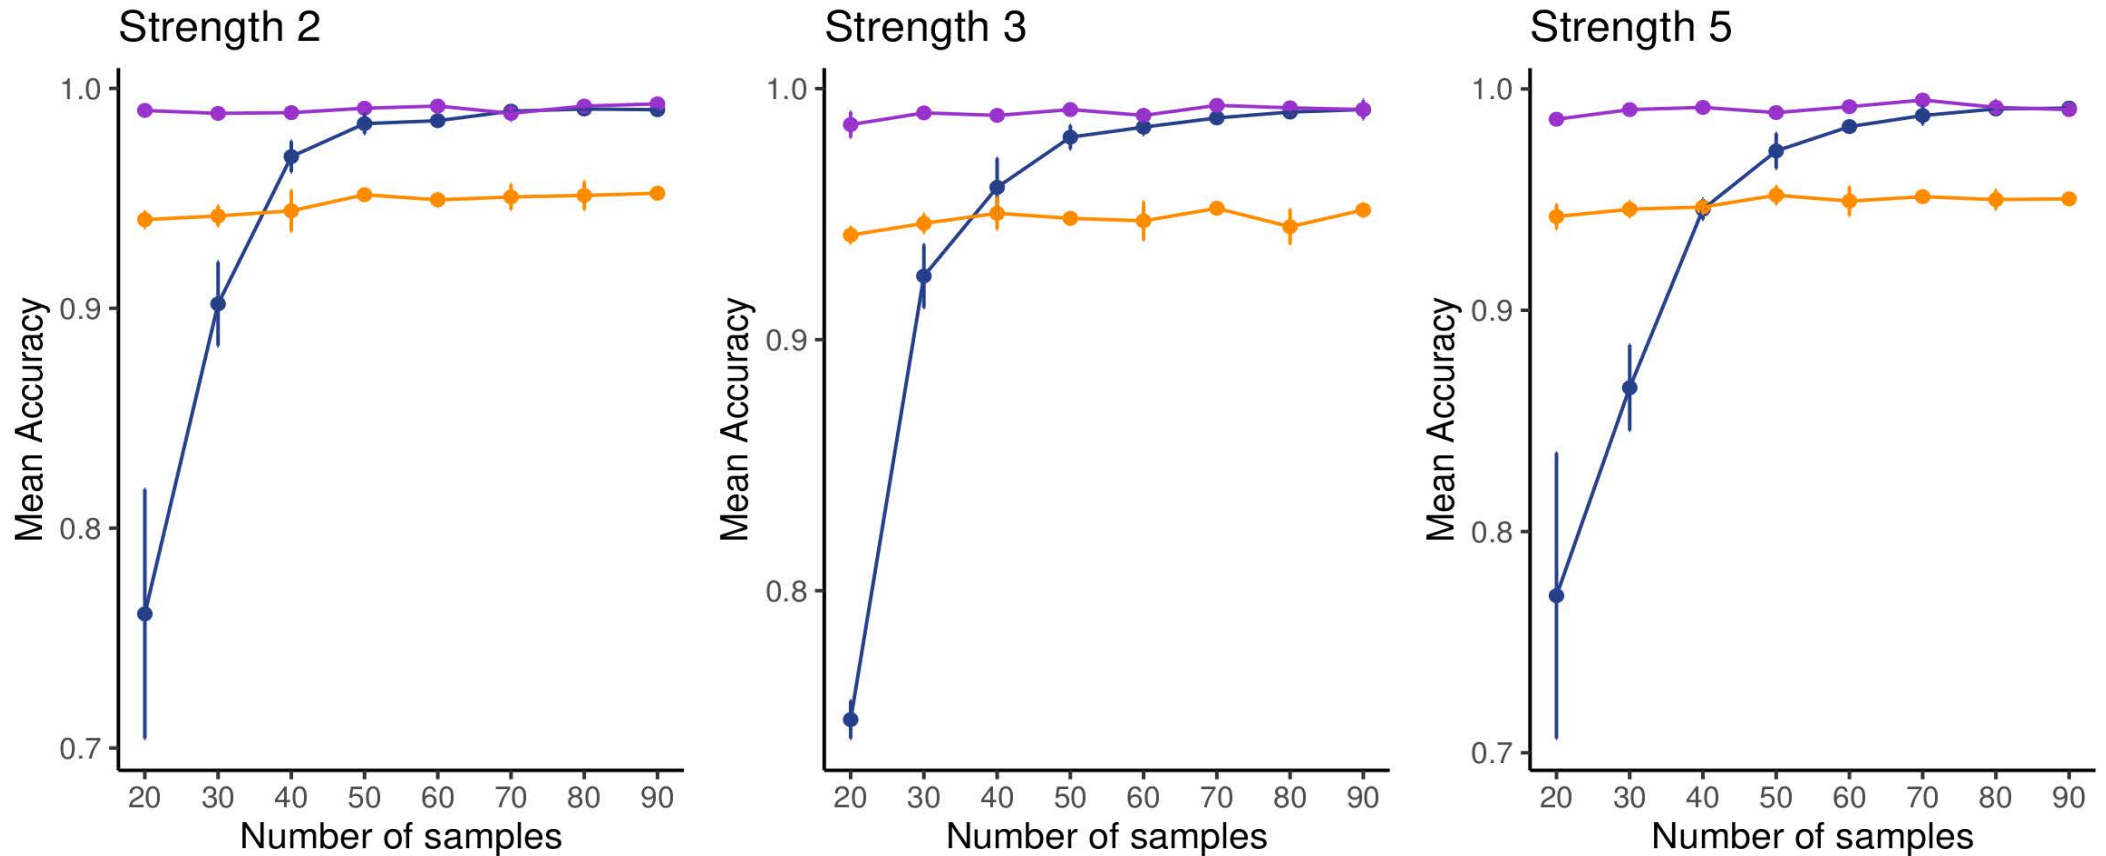

# Testing InIntE

- Two stage process – i) using simulated data; and, ii) using real data...
- Use of computer generated data for ecological interactions, as proposed by Weiss et al. (2016)
- Different strengths of interaction
- 4 types of interactions simulated (commensalism, competition, mutualism and amensalism)
- Tested on real metabarcoding data from grapevine leaves in different vineyards
- Vineyards were affected by downy mildew, caused by *Plasmopara viticola*

# Accuracy of interaction selection, as evaluated using computer generated data

Methods:  InfIntE  SparCC  SPIEC-EASI

$$Accuracy = \frac{TP + TN}{N}$$

# Accuracy of interaction classification for 60 samples

# Accuracy of interaction classification for 60 samples

# Accuracy of interaction classification for 60 samples

# Accuracy of interaction classification for 60 samples

# Using real metabarcoding data

## Vineyard locations

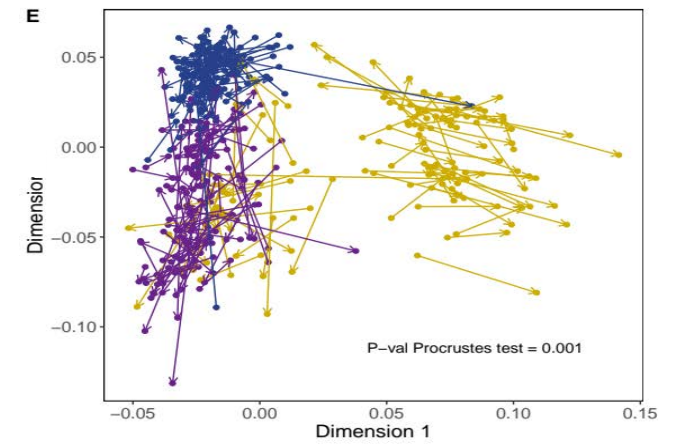

A

## Pathogen concentration

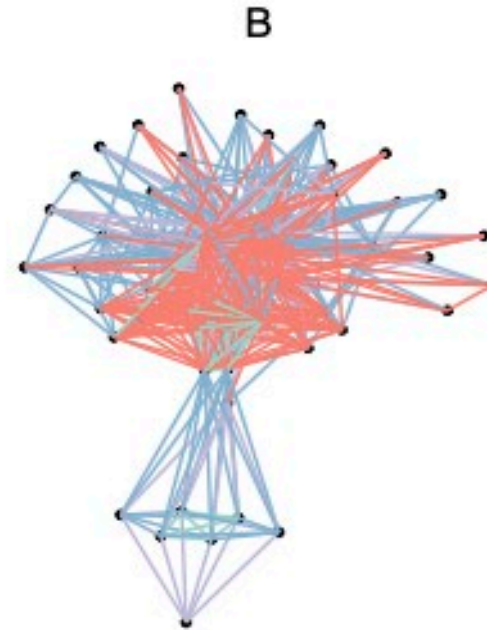

## Sample ordination

# Networks reconstructed using real data

Interaction Type	Effect on OTU1	Effect in OTU2
Amensalism	down	null
Commensalism	up	null
Competition	down	down
Mutualism	up	up
Predation	up	down

# Validating a sub-network:

- Negative interactions with the pathogen *P. viticola*
- Searched using keywords:
  - *P. viticola* antagonist
  - Biocontrol

# Conclusions

- InflntE: Interaction inference tool based on explainable machine learning
- Identified key network comparison measures
- Potential use for identifying biocontrol agents and biomonitoring

# Perspectives

- Introduction of background knowledge (databases) and new interaction hypothesis to InflntE
- Large scale testing of the InflntE R package
- Application to automated biomonitoring

# Sharing InflntE

- Coded in an R package
- Easy to install
- Tutorial Vignette
- Complemented by a network visualization app

# Which method should I choose?

## Correlation based

### Pros

---

- Robust to biases such as composition or abiotic effects
- Can work with smaller sample sizes
- Fast
- Widely used

### Cons

---

- Requires interpretation
- Does not use domain or background knowledge

## InflntE

### Pros

---

- Explainable detection and classification of interaction types, using composition
- Accuracy comparable to statistical methods
- Reconstruction of networks of diverse interaction types
- Flexibility: new uses of interaction hypotheses and background knowledge

### Cons

---

- Needs larger sample sizes than correlation
- Longer execution times (but improving)

So, could we learn macro- networks?

# The FSE data

- 256 fields
- Split-field design

Beet

Betterave

Maize

Maïs

S. Rape

Colza de  
printemps

W. Rape

Colza  
d'hiver

# Sampling

# Sampling

- 1.5 million weed plants counted
- 1 ton (dried) plant biomass sorted
- > 2.5 million invertebrates trapped
- > 1400 km of pollinator transects walked

# The question

- Can we construct food webs synthetically, using currently available data?
- Are functional explanations of the ecosystem useful?

# Trophic model - data

- Herbicide removes food and shelter - something to eat and somewhere to sit
- Species Y will move to new habitat or die - measured as  $R_Y$ , where  $R_Y = \log_{10}(Y_{GM}/Y_C)$
- Species X, which feeds on Y, will change with Y as  $R_X$
- *Expectation* that:  $R_X$  is 'trophically' related to  $R_Y$

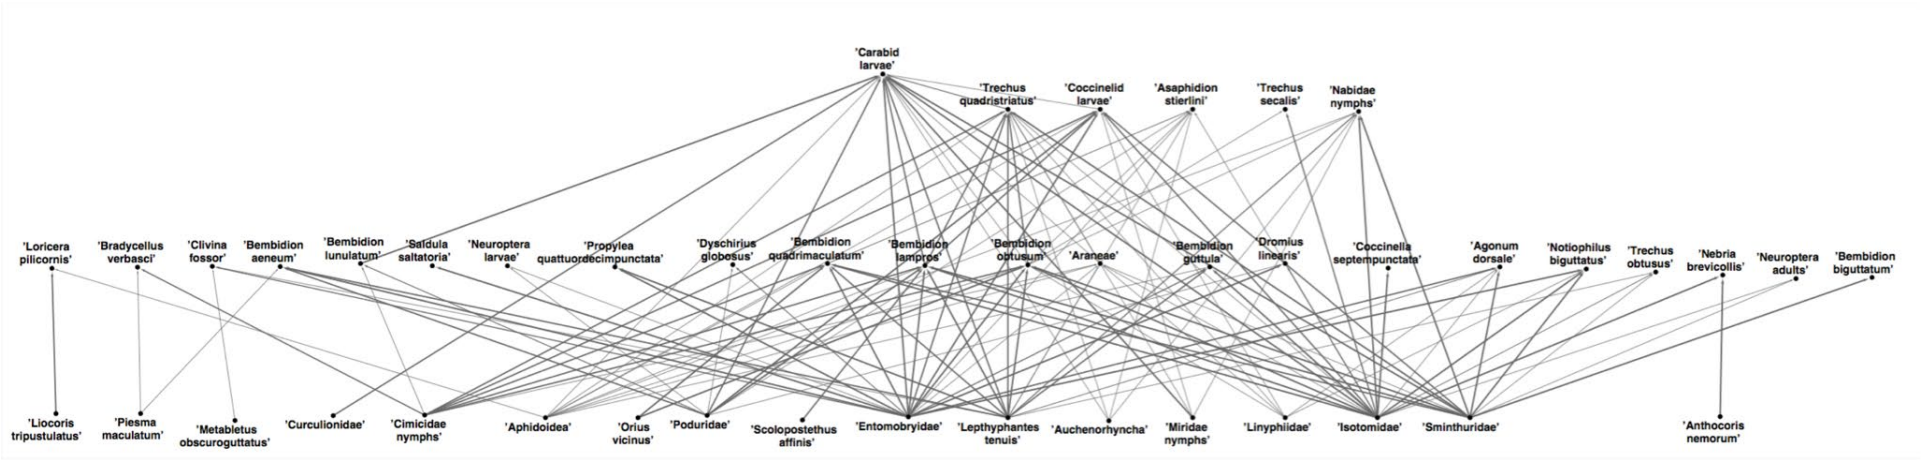

# Background information

- Appropriate mouthparts for feeding
- In any sample Y and X should co-occur
- Big things eat small things
- With this set of 'rules' we 'learn' food webs

Codified in Inductive Logic Programming  
system, Progol5.0

```
abundance(X, S, up):-  
  predator(X),  
  co occurs(S, X, Y),  
  bigger than(X, Y),  
  abundance(Y, S, up),  
  eats(X, Y).
```

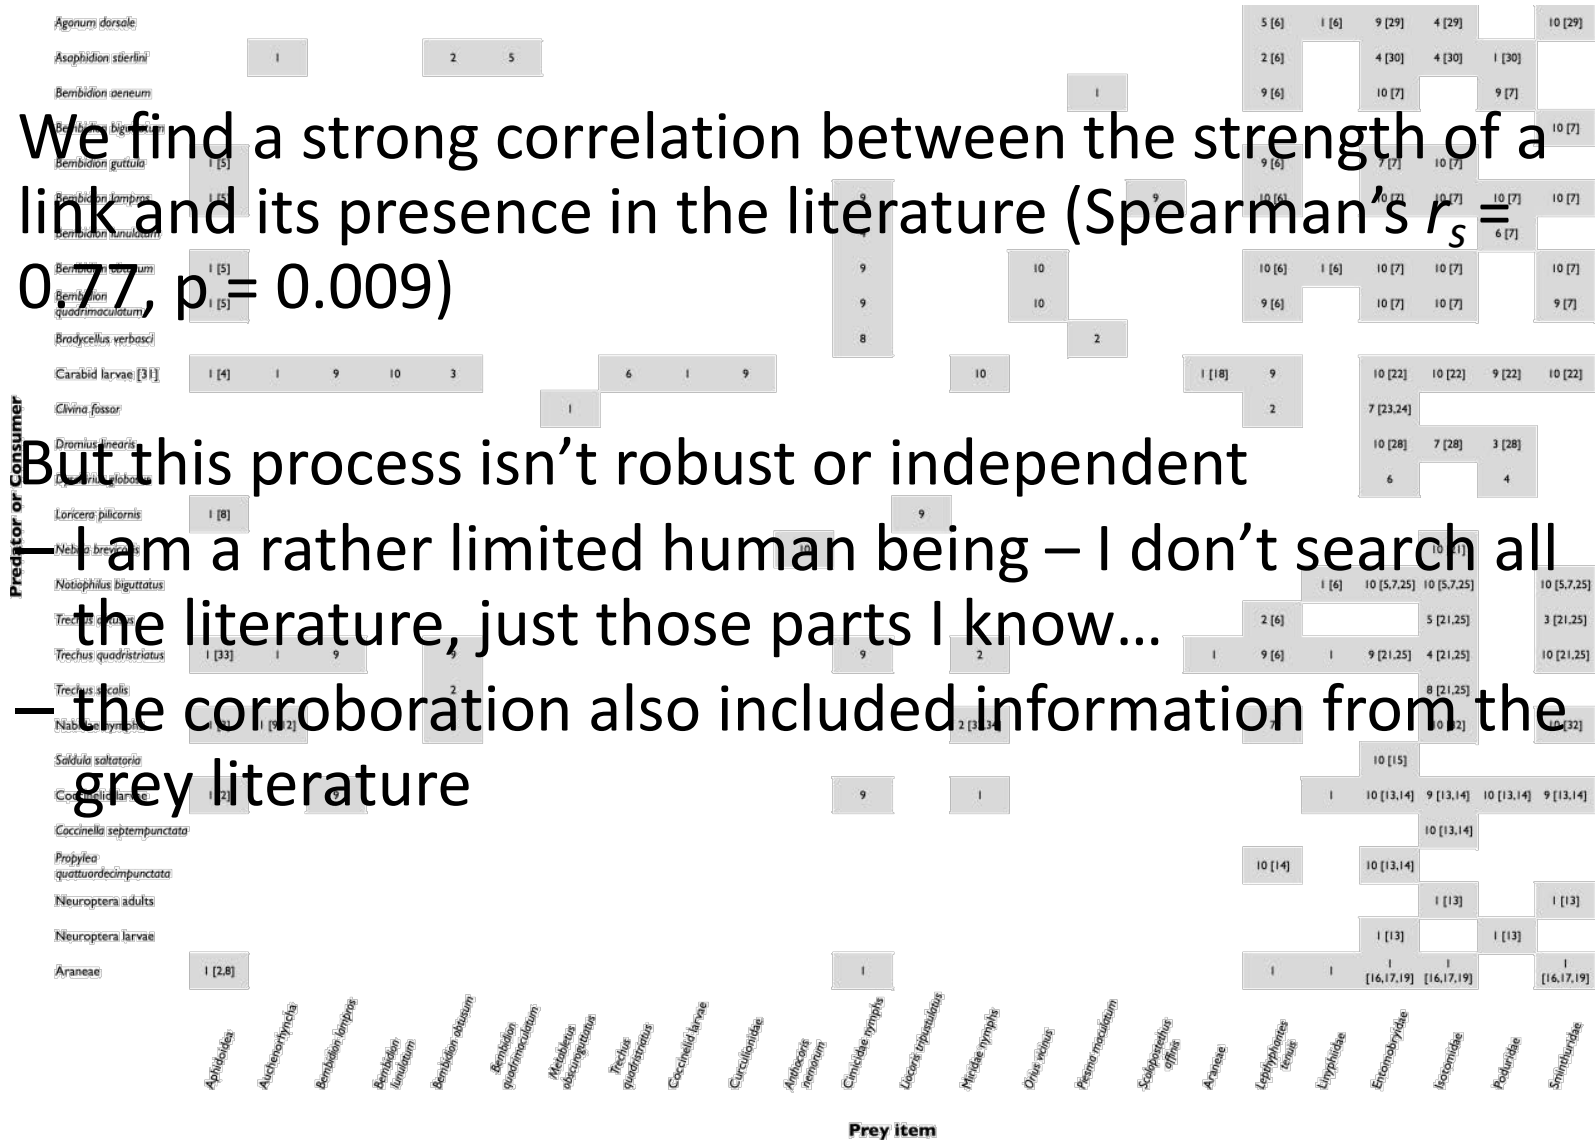

- 45 invertebrate species or taxa (~25%), but about 74% of the individuals were linked
- The literature corresponds with learnt links
- Collembola important prey. Carabid beetles were the dominant predators. Carabid larvae predators of a wide variety of prey.
- Lots of intraguild predation

# Validation

- We find a strong correlation between the strength of a link and its presence in the literature (Spearman's  $r_s = 0.77$ ,  $p = 0.009$ )

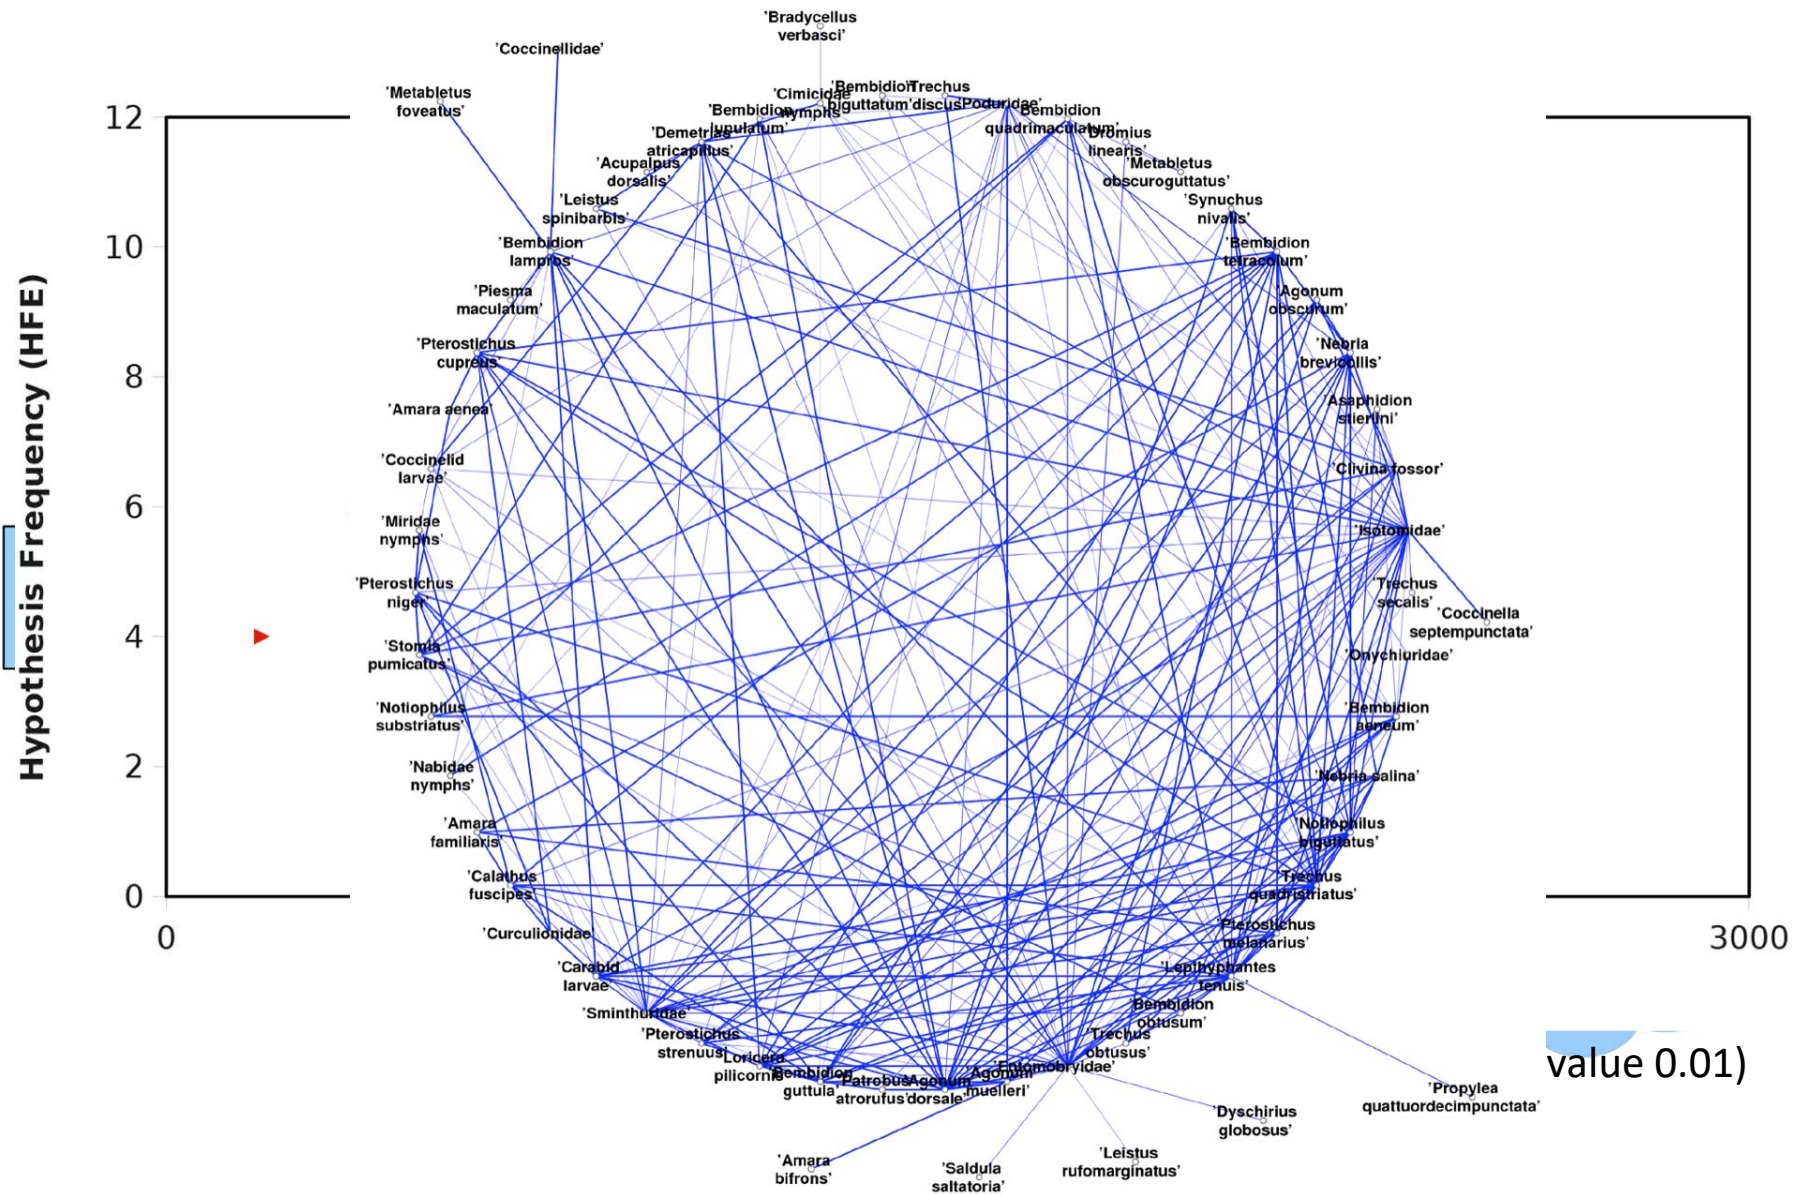

- But this process isn't robust or independent

- I am a rather limited human being – I don't search all the literature, just those parts I know...
- the corroboration also included information from the grey literature

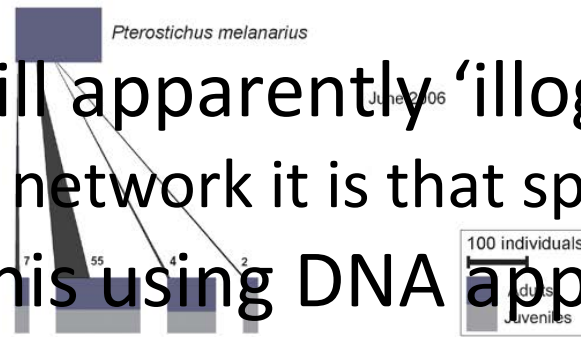

# Automatic literature verification

# Problems

- There are still apparently ‘illogical’ links...
  - » In the vortis network it is that spiders act as prey
- We tested this using DNA approaches

- and... it would seem that spider do indeed act as prey in this network

# Functional grouping...

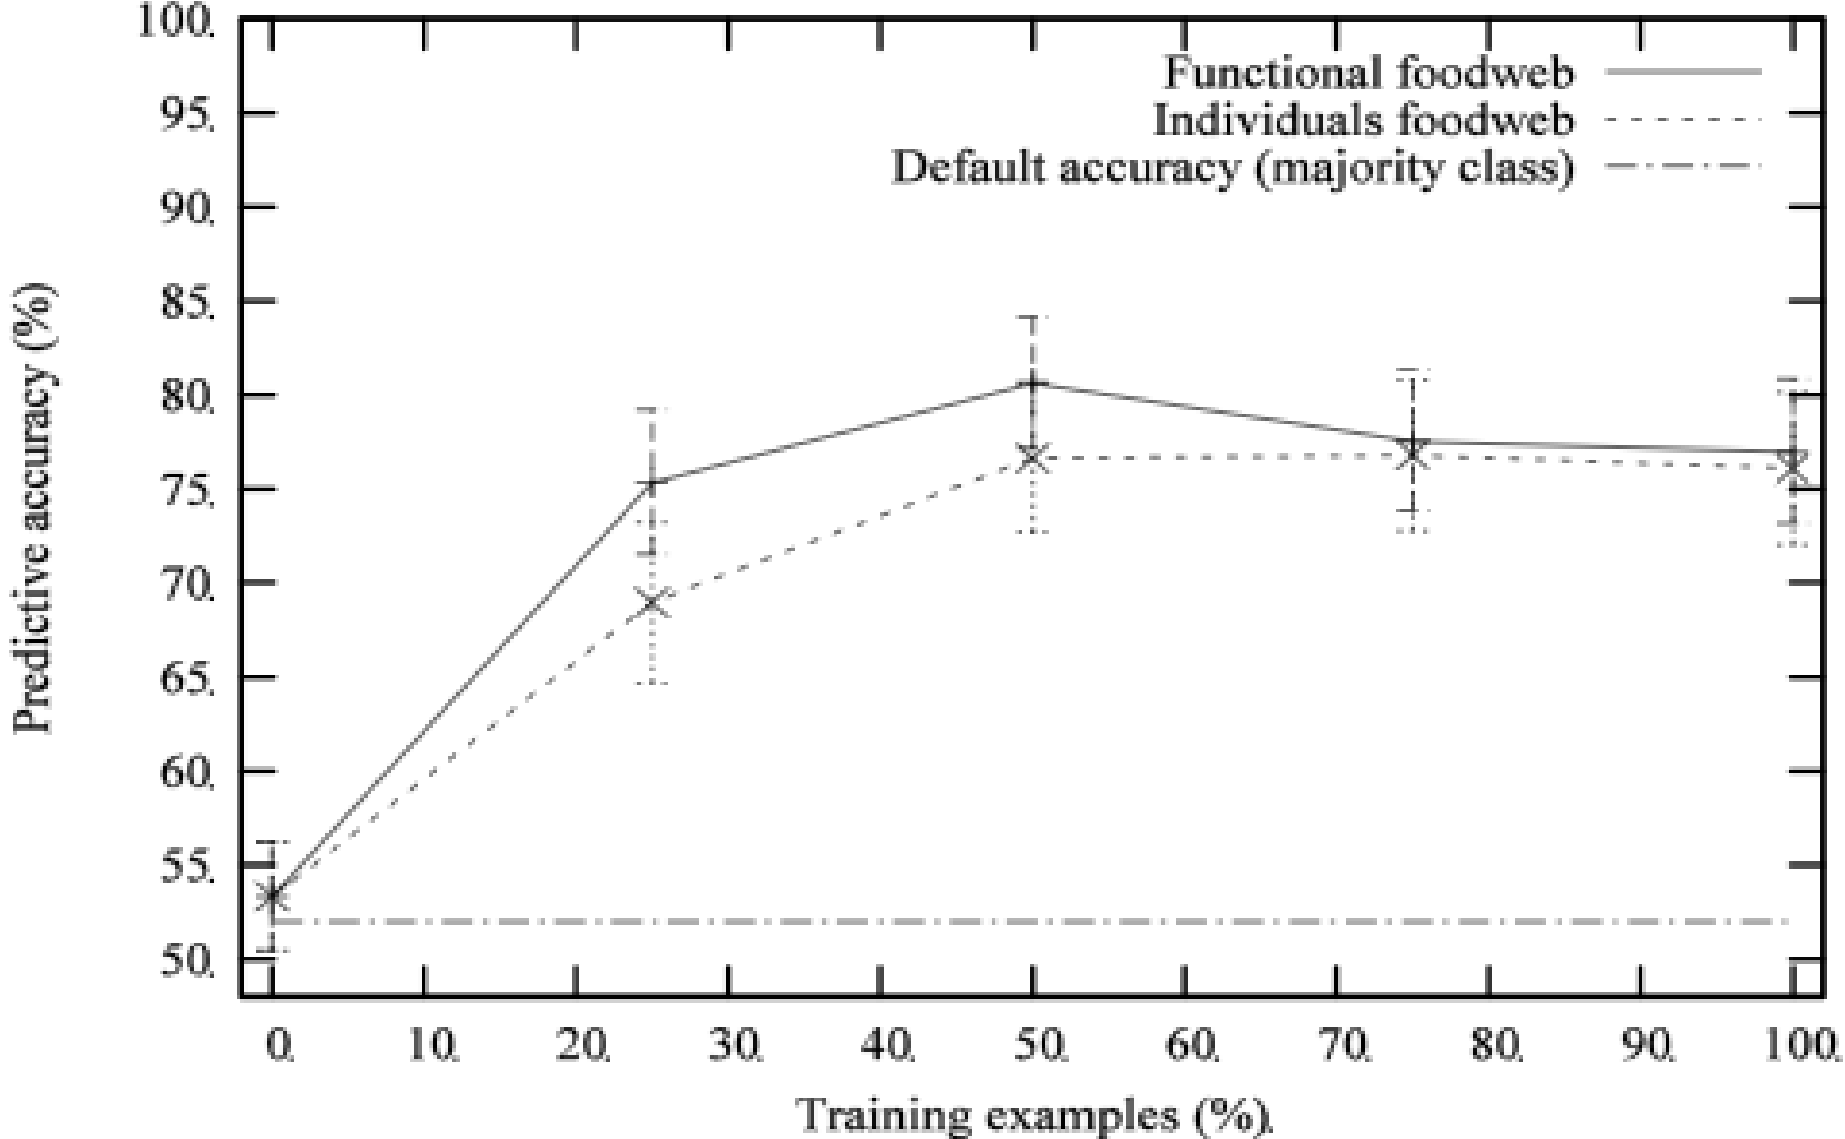

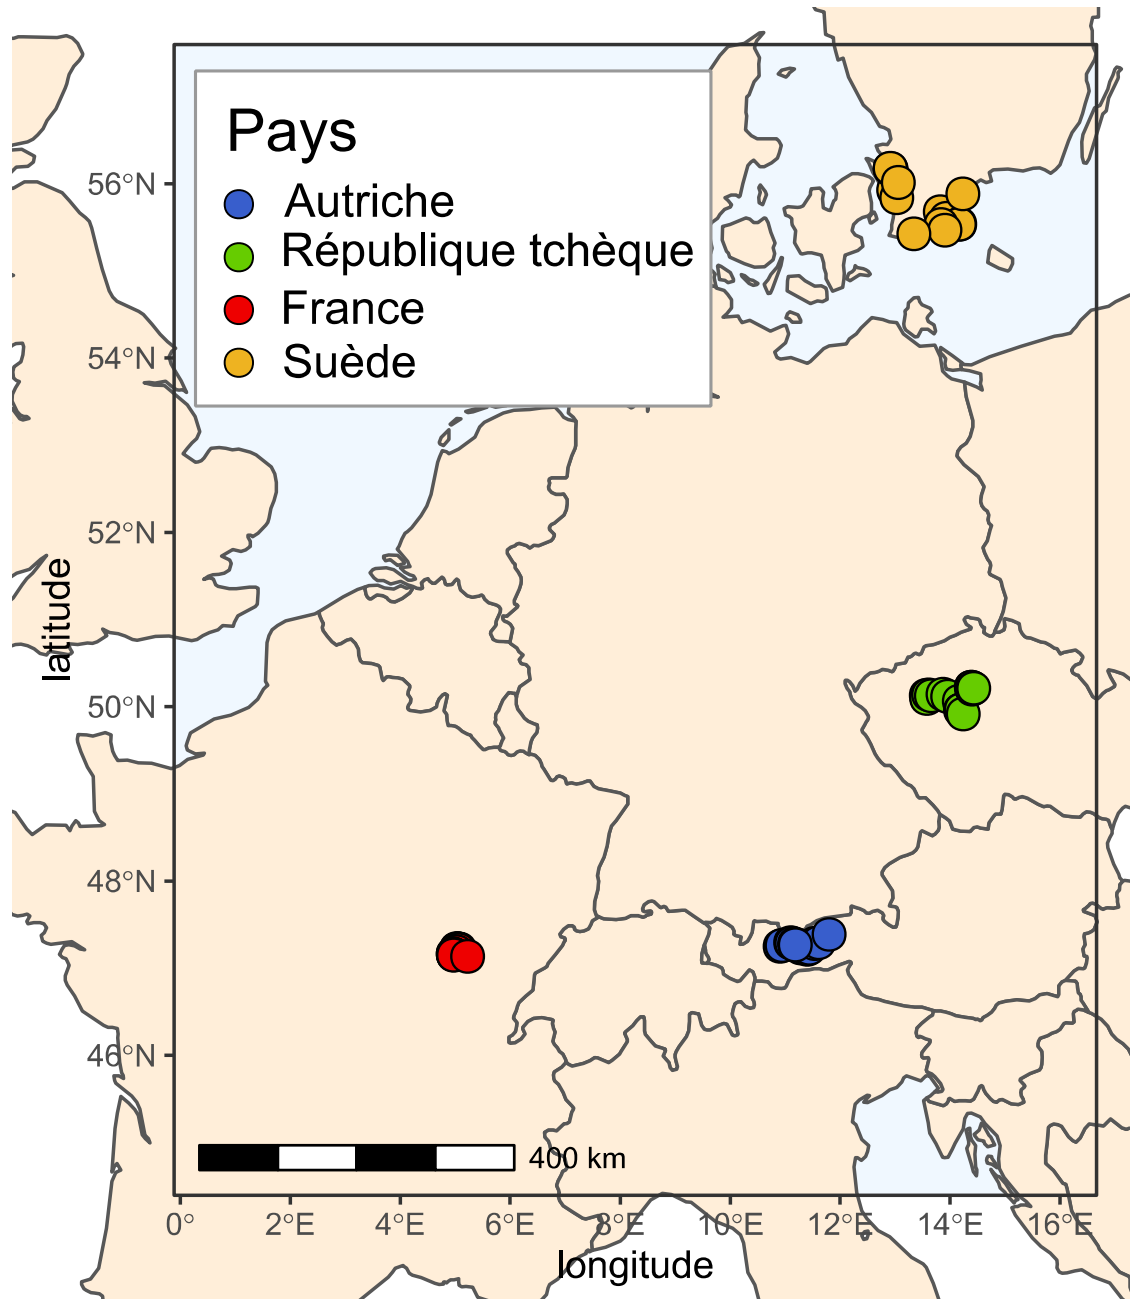

- Trophic behavior; Body size; Activity pattern.
- 182 species present ~ 17 functional types.
- We recreated a data-set of R-values, this time for functional groups rather than species

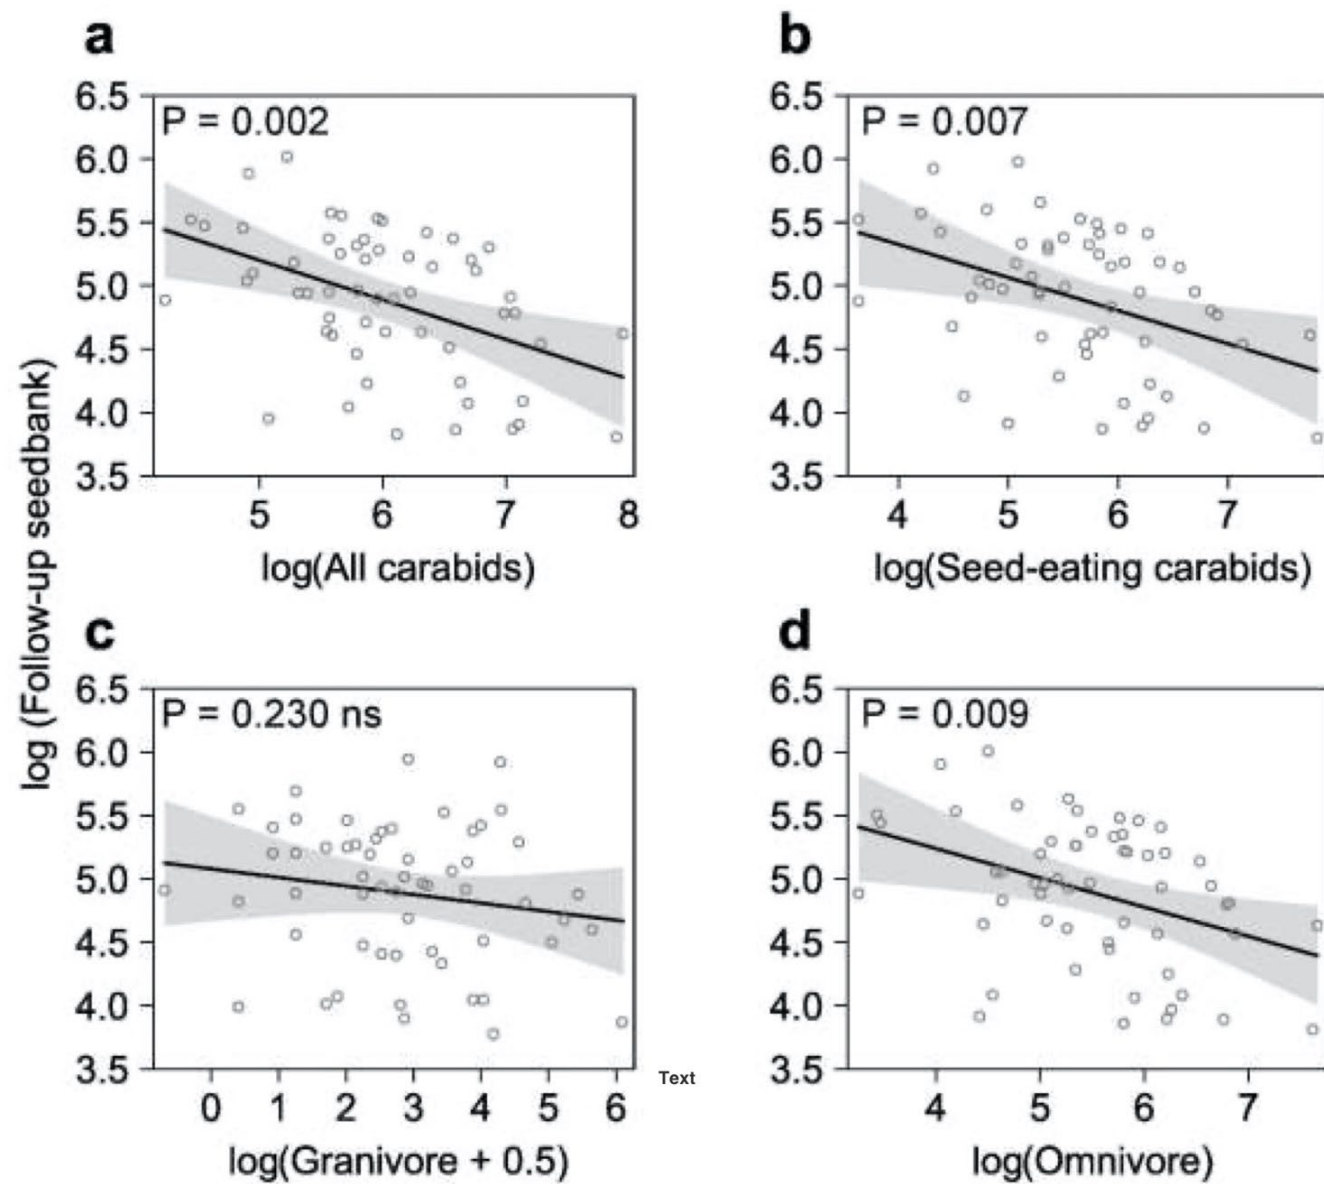

Preserves the structure found previously -  
detritivores at bottom, carabids at the top and lots  
of intra guild predation

# Overall learning curves for functional vs individual food-webs (Vortis)

**Figure 1.** Multiple linear regression model fits to test the weed seedbank regulation by carabids. The log(Follow-up seedbank) is plotted against the log-transformed AD of: (a) all occurring carabid species; (b) seed-eating; (c) granivore; and, (d) omnivore carabids in session 2. The line represents the fixed-effect prediction and associated 95% confidence intervals (shaded), with the open circles being the partial residuals. Negative slopes indicate a regulatory effect of carabid AD on the seedbank. The plot is created using R version 3.6.1 and the package effects.
